

STM32L5 - DAC

Digital-to-Analog Converter
Revision 1.0

Hello, and welcome to this presentation of the STM32L5 digital-to-analog converter.

This block is used to convert digital signals to analog voltages which can interface with the external world and also with on-chip peripherals such as comparators and operational amplifiers.

- Converts digital data to analog output voltage
 - 8- or 12-bit modes
 - One DAC module with two output channels
 - Low-power Sample & Hold mode

Application benefits

- On-chip DAC can control the external bias circuitry, replacing potentiometers
- It can also serve as a voice and arbitrary signal generator

The STM32L5 digital-to-analog converters converts 8- or 12-bit digital data to an analog voltage.

DAC module has two converters that can work synchronously or asynchronously.

A low-power Sample and Hold mode is also integrated.
The DAC can interface with external potentiometers or bias circuitry.

It can also create voice and arbitrary signals.

Key features

3

- 8- or 12-bit mode
- DAC output channel buffered or non buffered
- Sample and Hold mode for low-power applications
- Synchronized update capability
- DMA capability
- Noise-wave, triangular-wave generation
- Complex triggering system

The digital-to-analog converter inside STM32L5 microcontrollers offers simple digital-to-analog conversion in an 8- or 12-bit mode.

The DAC outputs can have a low impedance buffer to drive external loads.

Its Sample and Hold mode can reduce the power consumption significantly.

The two converters within the same DAC can be synchronized with each other.

The input data can be transferred by DMA which offloads the CPU.

It also integrates small logic to generate noise and triangle waveforms.

The DAC output data is updated by a complex triggering system, based on software request, timers and EXTI.

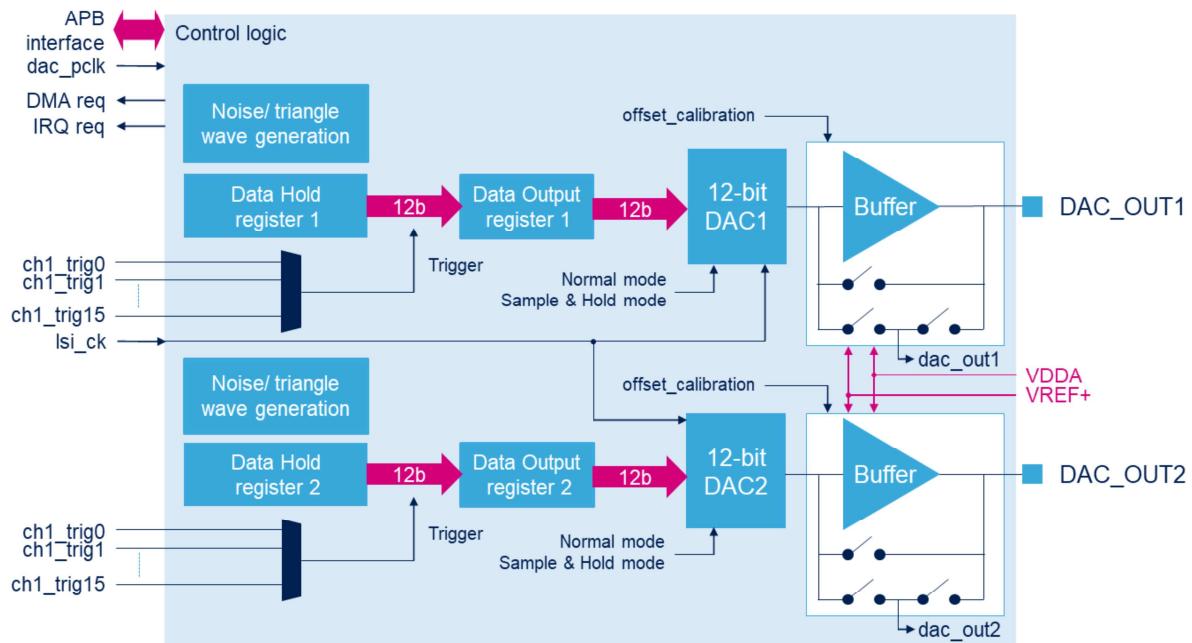

- VREF+ pin used as reference voltage
 - Can be driven by internal VREFBUF output: 2.048V, 2.5V
 - Or external reference connected to VREF+ pin
- Buffer calibration:
 - Offset calibration only
 - Factory calibration loaded at DAC reset
 - User trimming

VREF+ is used as a positive voltage reference. An input reference pin, VREF+ (shared with other analog peripherals) is available for better resolution. An internal reference voltage buffer can generate the reference voltage on the same pad. Output buffer's voltage offset is calibrated. This calibration is performed at the factory, loaded after reset. The user calibration can be done when the operating conditions differs from nominal factory calibration conditions and in particular when VDD/VDDA voltage, temperature, VREF+ values change and can be done at any point during application by software.

Block diagram

5

Here you can see the simplified block diagram of the digital-to-analog converter.

This DAC block is supplied by VDDA and uses VREF+ as a voltage reference.

The digital-to-analog converter is an APB slave that supports DMA requests to fill the data hold register.

Either of the DAC_OUTx signals can be disconnected from the corresponding output pin which can be used as an ordinary GPIO.

DAC_OUTx signals can use an internal pin to connect to on-chip peripherals such as comparators and OPAMPs.

DAC output channels are buffered or non-buffered.

Sample and hold block use LSI (Low-Speed Internal oscillator) clock source and are operational in Stop mode for static conversions.

The content of the Data Hold registers is transferred to the

corresponding Data Output register when a trigger condition is detected, this includes software triggers. Then the content of the Data Output register is transferred to the converter. The output buffer has mechanism to calibrate the voltage offset.

DAC channels configuration

6

DAC features	DAC1
Maximum sampling time	1Msps
Output buffer	x
Number of channels	2 (external)
IO connection	CH1 on PA4 CH2 on PA5

- DAC speeds:
 - 1MHz:
 - 3 external channels (DAC1_OUTx, DAC2_OUT1)
 - Buffered/unbuffered mode

The STM32L5 implements one DAC unit.

DAC1 supports two channels.

DAC1 can output to GPIOs. And it can be connected to COMP and OPAMP units.

The utilization of output buffers is optional for DAC1.

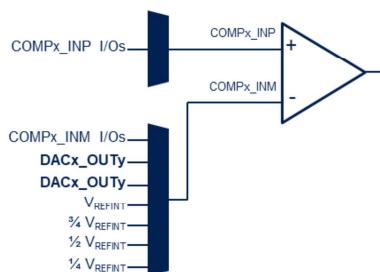

DAC1 maximum speed is 1 Mega sample per second.

DAC internal outputs

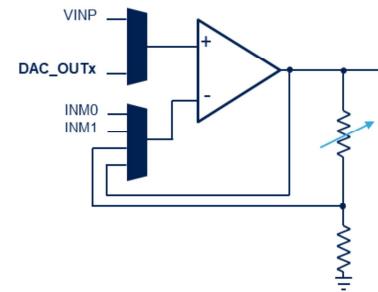

7

- DAC output as internal signal only:
 - The DAC output channel can be disconnected from the DAC_OUTx output pin and can be connected to on-chip peripherals only
 - Corresponding DAC_OUTx pin can be then used for another purpose

Using the output of DAC as a COMP INM input (COMP1-2)
➤ Reference voltage for comparator (DC, waveform generation)

Using the output of DAC as a OPAMP VINP input (OPAMP1-2)
➤ Way to get internal DAC channels to pin (OPAMPx_VOUT)

The dac_outx can use an internal pin connection to on-chip peripherals such as comparator and operational amplifier.

The DAC_OUTx GPIO can be used for another purpose. Connecting the internal DAC output to a COMP INM input defines the reference voltage of the comparator. Connecting the internal DAC output to an OPAMP VINP input can be used to bias the OPAMP DC point or amplify the analog voltage.

DAC data formats

8

Flexible data input formats

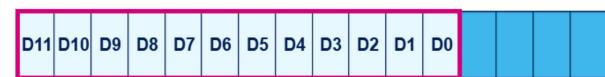

- 8-bit mode:

- Right-aligned data input (on 16-bit data register)

- 12-bit mode:

- Right-aligned data input (on 16-bit data register)
- Left-aligned data input (on 16-bit data register)

The DAC can support different input formats.

In 8-bit mode, it is a right-aligned 8-bit data format.

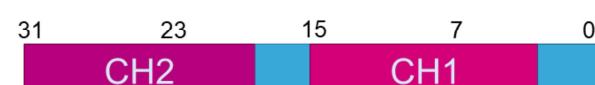

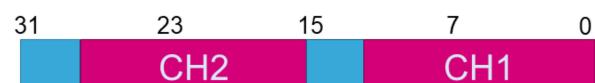

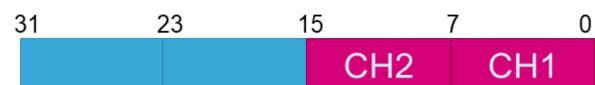

It also accepts the unsigned and signed data format.

DAC data formats

9

Dual-channel mode

- 8-bit mode:
 - 8-bit + 8-bit data input for Dual-channel mode
- 12-bit mode:
 - 12-bits + 12-bits Right-aligned data input for Dual-channel mode
 - 12-bits + 12-bits Left-aligned data input for Dual-channel mode

In Dual-channel mode, it is an 8-bit plus 8-bit data format, in order to provide input data for two DACs.

In 12-bits + 12-bits, either a right- or left-aligned mode can be used for input data.

Data held in these registers are transferred to the related converters either synchronously (for instance, for stereo audio) or asynchronously.

This means that the two channels can operate independently.

DAC conversion triggers

10

Several triggers for starting the DAC

- Conversions can be started:
 - Automatically by writing to the Data Hold register (software trigger)
 - The DAC_DHRx register to the DAC_DORx register takes only one APB clock cycle
 - By a triggered conversion:
 - 10 different timer outputs
 - External I/O trigger
 - Setting the software trigger bit
 - The following table indicates what is the delay between trigger and DAC_DOR update

HFSEL	APB frequency	Function
0	≤ 80 MHz	DAC_DOR update rate up to 3 APB clock cycles
1	> 80 MHz	DAC_DOR update rate up to 8 APB clock cycles

DAC output conversion is started by writing to the Data Hold register using software.

10 different timer outputs and an external I/O or software can trigger a DAC conversion.

When a software trigger is used, the content of the Data Hold register is transferred to the corresponding Data Output register after 1 APB clock cycle.

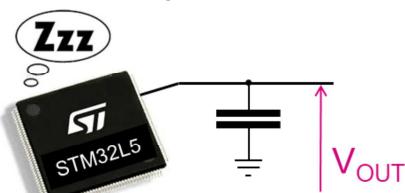

When a trigger occurs in Trigger mode, the content of the Data Hold register is transferred to the corresponding Data Output register after 3, or 8 APB clock cycles, depending on the APB clock frequency.

Sample and Hold feature

11

Low power mode

- The main goal of the “Sample & Hold” feature is to maintain the DAC output voltage when the MCU is in low-power operation in Stop0/1 mode
 - LSI clock remains active while dac_pclk clock is gated
- When configured in “Sample & Hold” mode, the DAC is able to output the converted voltage when all its related Analog and Digital circuitries are turned OFF
- An Internal or External Hold capacitor can be connected to a DAC output

The Sample & Hold feature maintains the DAC output voltage while not actively driving continuously.

It relies on an internal or external capacitor that will hold the voltage level at the end of the sample period.

Then the DAC output can be set in high impedance.

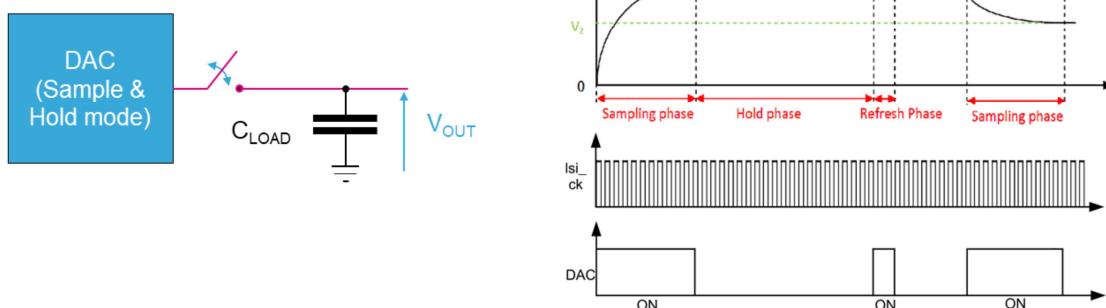

Of course the capacitor will discharge over time. That is why a refresh period has been defined. Upon expiration of the refresh period, the DAC output will be actively driven again to recharge the capacitor.

Sample and Hold feature

12

Low power mode

- The DAC conversions during “Sample & Hold” mode are made of three phases:
 - Sampling phase**
 - During this phase, the “Sample & Hold” element is charged into the desired voltage
 - Holding phase**
 - During which the DAC’s output is tri-stated (High-Z) to maintain the “Sample & Hold” element’s stored electrical charge
 - Refresh phase:**
 - Due to leakage coming from several sources, a refresh phase is essential to keep the output voltage at the desired value (+/- LSb)

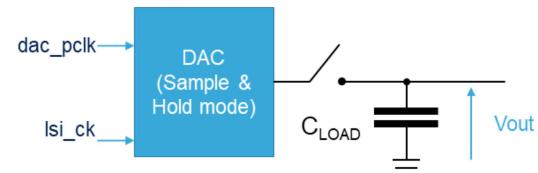

The digital-to-analog converter can work intermittently, charge the external or internal capacitor, and be powered down while the output voltage is kept on the hold capacitor. After the refresh period, the DAC is powered back on again and recharges the hold capacitor.

Sample and Hold feature

13

Low power mode

- “Sample & Hold” feature is available for extremely low power requirements
- Sample, Hold and Refresh timings are configurable
- In this mode, the DAC core and all corresponding logic and registers are driven by the Low Speed Internal oscillator clock (lsi_ck)

When the DAC is configured in “Sample & Hold” mode, it is able to generate its converted output voltage, and active circuitry can be turned off.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI clock (lsi_ck) in addition to the dac_pclk clock, allowing the usage of the DAC channels in Deep-low-power modes such as Stop mode.

The logic in charge of scheduling refreshes only requires the LSI clock.

In doing so, the DAC is only active during very low duty cycles: sample and refresh; resulting in very low power consumption.

The duty cycle program is very flexible and autonomous.

Sample and Hold feature

14

Low power mode

- “Sample & Hold” element (Internal or External)
 - When configured to be external: an external capacitor should be mounted on the DAC’s external pin
 - Buffer can be enabled or disabled
 - DAC output can be routed or not to internal components (i.e. embedded comparators)
 - When configured to be internal: an embedded capacitor is used as “Sample & Hold” element
 - In this configuration, the DAC output is routed only to internal components (on-chip comparators, etc.)
- Conversion phase timing
 - All conversion phase timings are made in reference to LSI clock source
 - Sampling, Hold and Refresh timings are configurable

The capacitor can be external or internal.

When it is external, the buffer can be used and the DAC’s output can also be routed to internal components, such as embedded comparators.

When it is internal, an embedded capacitor is used and the DAC’s output is routed only to internal components.

The charging time depends on the capacitor value.

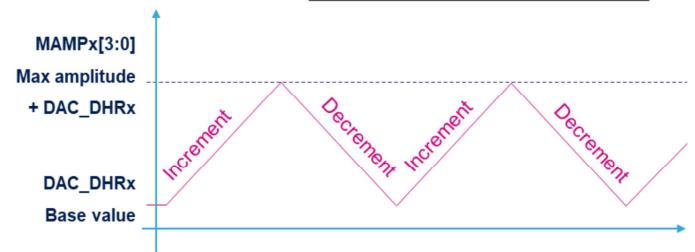

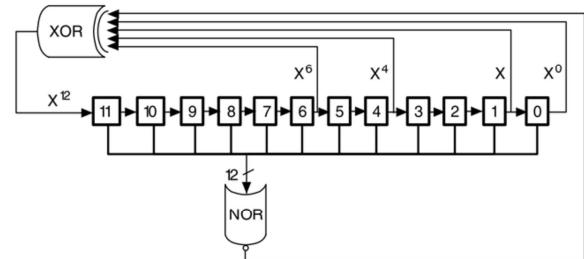

The timings for the three phases above are in units of lsi_ck clocks cycles.

Noise and triangle wave generation

15

Wave generation

- Noise generation
 - Based on the LFSR (Linear Feedback Shift Register)
 - Calculated noise value is added to the Data Hold register without overflow using an external trigger
 - Configurable amplitude
- Triangle generation
 - Based on the up-down counter, a triangle waveform can be generated (each trigger increments a +/- 1 step)
 - Configurable base and amplitude

The DAC digital interface integrates two special signal generators: noise and triangle waves.

The Linear Feedback Shift register can create the noise signal for the DAC input.

Each trigger updates the DAC output data by an LFSR block.

The up-down counter with a programmable count value can create triangle wave data which can update the DAC output data.

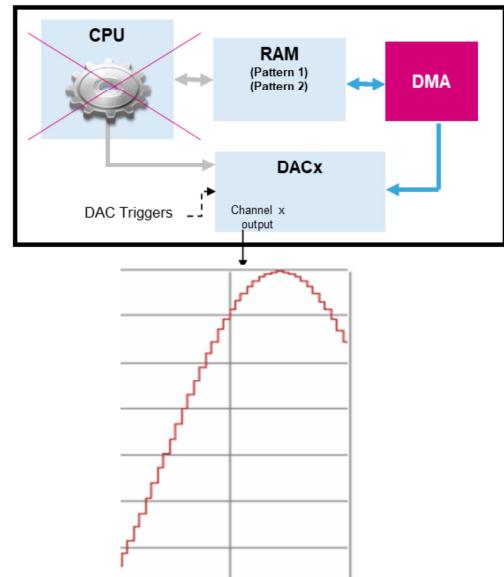

The data can also be updated by a trigger signal.

DAC with DMA

16

Offloads the CPU

- A DAC DMA request is generated when an external trigger occurs:
 - The Data Hold register value is then transferred to the Data Output register
 - Can generate a stable sampling time based output (timer controlled)
- DMA underrun with interrupt capability

The DAC can also issue DMA requests from the trigger signal.

Once a trigger is detected, the Data Hold register value is then transferred to the Data Output register.

Then the DMA request is generated to obtain the new data for the Data Hold register.

As the update of the Output Data register is initiated directly by the trigger signal, the DAC output signal will not have jitter, so that it can create a stable sampling time signal output, making it easy to filter out the sampling frequency.

Interrupts and DMA

17

Interrupt event	Description
DMA underrun	When a DMA request is not processed by the next external trigger

DMA event	Description
DMA request	External trigger when the DMAENx bits are set

To transfer data from memory, a DMA request can be generated.

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment of the first external trigger is received (first request), then no new request is issued and an underrun flag is set that causes a maskable interrupt request.

Low-power modes

18

Mode	Description
Sleep	No effect, DAC used with DMA
Low power Run	No effect
Low power Sleep	No effect, DAC used with DMA
Stop 0/ Stop 1	DAC remains active with a static value, if Sample & Hold mode is selected using the LSI clock
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby or Shutdown mode
Shutdown	

The digital-to-analog converter is active in the following low-power modes: Run and Sleep.

In Stop 0 and Stop1 modes, it remains active when Sample & Hold mode is selected.

In Standby and shutdown modes, the DAC is powered-down and it must be reinitialized afterwards.

Performance

19

	Condition	Value (typical)	Unit
VDDA		1.8 ~ 3.6	V
Monotonicity		10	bits
Differential Non Linearity (DNL)	(max)	+/-2	LSB
Integral Non Linearity (INL)	(max)	+/-4	LSB
Effective Number Of Bits (ENOB) 1 kHz output	Buffer on	11.4	bits
	Buffer off	11.5	bits
Consumption from VREF+ (1 Msps)	Buffer on	185	µA
	Buffer off	155	µA
Settling time (1 Msps)	+/-1 LSB, C = 50 pF	1.6	µs
Sampling rate		1.0	Msample/s

The following table shows some performance parameters for the digital-to-analog converter. The DAC can work between 1.8 and 3.6 volts.

When DAC output buffer is ON or DAC_OUT pin is connected, the minimum VDDA voltage value is 1.8V. 10-bit monotonicity is guaranteed.

When operating at 1 Mega sample per second, Power consumption is 185 µA when the buffer is enabled and 155 µA when the buffer is disabled.

By using Sample & Hold mode, the current consumption can be drastically reduced. Depending on the condition and the hold capacitor characteristics, less than 1 µA current consumption is possible for this mode. The DAC buffered output has a settling time of 1.6 µsec with 50 pF load.

The DAC can handle a sampling rate of 1 mega sample

per second.

Related peripherals

20

- Refer to these peripherals trainings linked to this peripheral:
 - VREFBUF- Voltage Reference Buffer
 - RCC- Clock module
 - DMA – Direct memory access
 - Interrupts – Nested Vectored Interrupt Controller
 - GPIO – General-purpose inputs and outputs
 - TIM – Timers
 - OPAMP – Operational Amplifier
 - COMP – Comparators

This is a list of peripherals related to the DAC. Please refer to these peripheral trainings for more information if needed.
